Prologue: Preliminaries 1

- 0.1 Signpost: *Uncertainty* 1
- 0.2 Discrete Probability Distributions 2
 - 0.2.1 A probability distribution summarizes our knowledge about an uncertain situation 2
 - 0.2.2 Conditional probability quantifies the degree to which events are correlated 4
 - 0.2.3 A random variable can be partially described by its expectation and variance 4
 - 0.2.4 Joint distributions 6
 - 0.2.5 Some explicit discrete distributions 7
- 0.3 Dimensional Analysis 9
- 0.4 Continuous Probability Distributions 10
 - 0.4.1 Probability density functions 10
 - 0.4.2 Some explicit continuous distributions 12
- 0.5 More Properties of, and Operations on, Probability Distributions 14
 - 0.5.1 Transformation of a probability density function 15
 - 0.5.2 The sample mean of many independent, identically distributed random variables has lower variance than any one of its constituents 15
 - 0.5.3 Count data are typically Poisson distributed 16
 - 0.5.4 The difference of two noisy quantities can have greater relative standard deviation than either by itself 16
 - 0.5.5 The convolution of two distributions describes the sum of their random variables 16
- 0.6 Thermal Randomness 17
- Big Picture 17
- Key Formulas 18
- Problems 19

PART I Doorways of Light

Chapter 1 | What Is Light? 23

- 1.1 Signpost: *Photons* 23
- 1.2 Light Before 1905 24
 - 1.2.1 Basic light phenomena 25
 - 1.2.2 Light displays wavelike behavior in many situations 25
- 1.3 Light Is Lumpy 26
 - 1.3.1 The discrete aspect of light is most apparent at extremely low intensity 27
 - 1.3.2 The photoelectric effect 30

x

1.3.3	Einstein's proposal	33
1.3.4	Light-induced phenomena in biology qualitatively support the Einstein relation	35
1.4	Background: Poisson Processes	35
1.4.1	A Poisson process can be defined as a continuous-time limit of repeated Bernoulli trials	35
1.4.2	Blip counts in a fixed interval are Poisson distributed	36
1.4.3	Waiting times are Exponentially distributed	36
1.5	A New Physical Model of Light	37
1.5.1	The Light Hypothesis, part 1	37
1.5.2	The spectrum of light can be regarded as a probability density times an overall rate	38
1.5.3	Light can eject electrons from individual molecules, inducing photochemical reactions	39
1.6	Fluorescence and Photoisomerization Can Occur after Photon Absorption	40
1.6.1	The Electron State Hypothesis	40
1.6.2	Atoms have sharp spectral lines	41
1.6.3	Molecules: fluorescence	42
1.6.4	Molecules: photoisomerization	45
1.7	Transparent Media Are Unchanged by the Passage of Light, but Slow It Down	47
	Big Picture	47
	Key Formulas	48
	Track 2	50
1.3.1'	Quantum randomness is distinct from classical chaos	50
1.3.3'a	The reality of photons	50
1.3.3'b	Light also carries momentum	51
1.3.3'c	The thermal radiation spectrum	52
1.3.3'd	The role of frequency	53
1.4'	Corrections to Poisson emission and detection	54
1.5.1'a	Gamma rays	54
1.5.1'b	More about the Light Hypothesis	55
1.5.3'	Mechanism of DNA photodamage	55
1.6.1'	Dense media	56
1.6.2'a	More about atoms and light	56
1.6.2'b	A Cauchy distribution in physics	56
1.6.3'a	Born-Oppenheimer approximation	57
1.6.3'b	Classical approximation for nuclear motion	57
1.6.3'c	Debye relaxation	58
1.6.4'	Fast conformational changes	58
	Problems	59
Chapter 2 Photons and Life 61		
2.1	Signpost: <i>Seeing and Touching</i>	61
2.2	Light-Induced DNA Damage	61
2.3	Fluorescence as a Window into Cells	62
2.3.1	Fluorescence can discriminate healthy from diseased tissue during surgery	62
2.3.2	Fluorescence microscopy can reduce background and specifically show only objects of interest	64
2.4	Background: Membrane Potential	66
2.4.1	Electric currents involve ion motion	66
2.4.2	An ion imbalance across the cell membrane can create a membrane potential	67
2.4.3	Ion pumps maintain a resting electric potential drop across the cell membrane	67
2.4.4	Ion channels modulate the membrane potential to implement neural signaling	68

2.4.5	Action potentials can transmit information over long distances	68
2.4.6	Creation and utilization of action potentials	69
2.4.7	More about synaptic transmission	70
2.5	Optogenetics	72
2.5.1	Brains are hard to study	72
2.5.2	Channelrhodopsin can depolarize selected neurons in response to light	73
2.5.3	Halorhodopsin can hyperpolarize selected neurons in response to light	74
2.5.4	Other methods	75
2.6	Fluorescent Reporters Can Give Real-Time Readout of Cellular Conditions	76
2.6.1	Voltage-sensitive fluorescent reporters	76
2.6.2	Split fluorescent proteins and genetically encoded calcium indicators	78
2.7	Two-Photon Excitation Permits Imaging Deep within Living Tissue	79
2.7.1	The problem of imaging thick samples	79
2.7.2	Two-photon excitation depends sensitively on light intensity	80
2.7.3	Multiphoton microscopy can excite a specific volume element of a specimen	81
2.8	Fluorescence Resonance Energy Transfer	83
2.8.1	How to tell when two molecules are close to each other	83
2.8.2	A physical model for FRET	85
2.8.3	Some forms of bioluminescence also involve FRET	87
2.8.4	FRET can be used to create a spectroscopic “ruler”	87
2.8.5	Application of FRET to DNA bending flexibility	89
2.8.6	FRET-based indicators	90
2.9	A Glimpse of Photosynthesis	93
2.9.1	It’s big	93
2.9.2	Two quantitative puzzles advanced our understanding of photosynthesis	93
2.9.3	Resonance energy transfer resolves both puzzles	96
	Big Picture	98
	Key Formulas	98
	Track 2	100
2.4.3’	More about membrane potentials	100
2.4.5’	Other uses for the resting potential	100
2.7.2’	The β -squared rule	100
2.7.3’	More about two-photon imaging	101
2.8.1’	About FRET and its efficiency	101
2.8.4’	Other experimental tests of FRET	102
2.8.5’	Why reported FRET efficiencies sometimes exceed 100%	102
2.9.3’	More details about the photosynthesis apparatus in plants	102
	Problems	103

Chapter 3 | Color Vision 107

3.1	Signpost: <i>A Fifth Dimension</i>	107
3.2	Color Vision Confers a Fitness Payoff	107
3.3	Newton’s Experiments on Color	108
3.4	Background: More Properties of Poisson Processes	110
3.4.1	Thinning property	111
3.4.2	Merging property	111
3.4.3	Significance for light	112
3.5	Combining Two Beams Corresponds to Summing Their Spectra	112

xii

3.6	Psychophysical Aspects of Color	113
3.6.1	$R+G$ looks like Y	113
3.6.2	Color discrimination is many-to-one	113
3.6.3	Perceptual matching follows quantitative, reproducible, and context-independent rules	113
3.7	Color from selective absorption	117
3.7.1	Reflectance and transmittance spectra	117
3.7.2	Subtractive color scheme	117
3.8	A Physical Model of Color Vision	118
3.8.1	The color-matching function challenge	118
3.8.2	Available wetware in the eye	119
3.8.3	The trichromatic model	121
3.8.4	The trichromatic model explains why $R+G\sim Y$	123
3.8.5	Our eyes project light spectra to a 3D vector space	124
3.8.6	A mechanical analogy for color matching	126
3.8.7	Connection between the mechanical analogy and color vision	127
3.8.8	Quantitative comparison to experimentally observed color-matching functions	127
3.9	Why the Sky Is Not Violet	129
3.10	Direct Imaging of the Cone Mosaic	130
	Big Picture	131
	Key Formulas	131
	Track 2	133
3.5'a	Flux, irradiance, and spectral flux irradiance	133
3.5'b	Combining spectra is a linear operation	133
3.6.3'a	Variation of color matching	133
3.6.3'b	Colorblindness	133
3.6.3'c	Tetrachromacy	134
3.7'	Perceptual color	134
3.8.3'a	Determination of sensitivity functions	135
3.8.3'b	Contrast to audition	135
3.8.4'a	Enhancement of color contrast in autofluorescence endoscopy	135
3.8.4'b	Spectral analysis can discriminate many fluorophores and their combinations	135
3.8.5'a	Photoisomerization rate regarded as an inner product	138
3.8.5'b	Correction to predicted color matching due to absorption	138
3.8.8'a	Relative versus absolute sensitivity	139
3.8.8'b	Simplified color space	139
	Problems	142

Chapter 4 | How Photons Know Where to Go 145

4.1	Signpost: <i>Probability Amplitudes</i>	145
4.2	Summary of Key Phenomena	146
4.3	The Probability Amplitude	150
4.3.1	Reconciling the particle and wave aspects of light requires the introduction of a new kind of physical quantity	150
4.4	Background: Complex Numbers Simplify Many Calculations	152
4.5	Light Hypothesis, part 2	154
4.6	Basic Interference Phenomena	156
4.6.1	Two-slit interference explained via the Light Hypothesis	156
4.6.2	Newton's rings illustrate interference in a three-dimensional setting	158

- 4.6.3 An objection to the Light Hypothesis 159
- 4.7 The Stationary-Phase Principle 161
 - 4.7.1 The Fresnel integral illustrates the stationary-phase principle 161
 - 4.7.2 The probability amplitude is computed as a sum over all possible photon paths 164
 - 4.7.3 Diffraction through a single, wide aperture 165
 - 4.7.4 Reconciliation of particle and wave aspects 168

Big Picture 170

Key Formulas 170

Track 2 172

- 4.2' On philosophically repugnant theories 172
- 4.5'a More about the Light Hypothesis 172
- 4.5'b More about uniform media 173
- 4.6.1' Which slit? 173
- 4.6.2' More about reflection 174
- 4.6.3' More objections 174
- 4.7.2'a The neighborhood of the stationary-phase path 176
- 4.7.2'b Nonuniform media 176

Problems 177

Chapter 5 | Optical Phenomena and Life 180

- 5.1 Signpost: *Sorting and Directing* 180
- 5.2 Structural Color in Insects, Birds, and Marine Organisms 180
 - 5.2.1 Some animals create color by using nanostructures made from transparent materials 180
 - 5.2.2 An extension of the Light Hypothesis describes reflection and transmission at an interface 183
 - 5.2.3 A single thin, transparent layer reflects with weak wavelength dependence 184
 - 5.2.4 A stack of many thin, transparent layers can generate an optical bandgap 186
 - 5.2.5 Structural color in marine organisms 188
- 5.3 Ray-optics Phenomena 190
 - 5.3.1 The reflection law is a consequence of the stationary-phase principle 190
 - 5.3.2 Transmission and reflection gratings generate non-ray-optics behavior by editing the set of allowed photon paths 191
 - 5.3.3 Refraction arises from the stationary-phase principle applied to a piecewise-uniform medium 192
 - 5.3.4 Total internal reflection provides another tool to enhance signal relative to noise in fluorescence microscopy 194
 - 5.3.5 Refraction is generally wavelength dependent 196

Big Picture 197

Key Formulas 197

Track 2 199

- 5.2.2' Transmission and reflection in classical electromagnetism 199
- 5.3.1' Fine points about reflection and refraction 200
- 5.2.4' More complicated layers 200

Problems 201

PART II Human and Superhuman Vision

Chapter 6 | Direct Image Formation 209

- 6.1 Signpost: *Bright Yet Sharp* 209
- 6.2 Image Formation Without Lenses 209
 - 6.2.1 Shadow imaging 209
 - 6.2.2 Pinhole imaging suffices for some animals 210
- 6.3 Addition of a Lens Allows Formation of Bright, Yet Sharp, Images 211
 - 6.3.1 The focusing criterion relates object and image distances to lens shape 212
 - 6.3.2 A more general approach 216
 - 6.3.3 Formation of a complete image 216
 - 6.3.4 Aberration degrades image formation outside the paraxial limit 218
- 6.4 The Vertebrate Eye 218
 - 6.4.1 Image formation with an air-water interface 218
 - 6.4.2 Focusing powers add in a compound lens system 221
 - 6.4.3 A deformable lens implements focal accommodation 222
- 6.5 Light Microscopes and Related Instruments 224
 - 6.5.1 “Rays of light” are a useful idealization in the ray-optics regime 224
 - 6.5.2 Real and virtual images 225
 - 6.5.3 Spherical aberration 225
 - 6.5.4 Dispersion gives rise to chromatic aberration 227
 - 6.5.5 Confocal microscopy suppresses out-of-focus background light 228
- 6.6 Darwin’s Difficulty 230
- 6.7 **Background:** Angles and Angular Area 230
 - 6.7.1 Angles 230
 - 6.7.2 Angular area 232
- 6.8 Diffraction Limit 232
 - 6.8.1 Even a perfect lens will not focus light perfectly 232
 - 6.8.2 Three dimensions: The Rayleigh criterion 234
 - 6.8.3 Animal eyes match their photoreceptor size to the diffraction limit 235
- Big Picture 236
- Key Formulas 236
- Track 2 239
 - 6.4’ The retinal pigment epithelium 239
 - 6.8.2’ The Abbe criterion 239
- Problems 240

Chapter 7 | Imaging as Inference 247

- 7.1 Signpost: *Information* 247
- 7.2 **Background:** On Inference 248
 - 7.2.1 The Bayes formula tells how to update a probability estimate 248
 - 7.2.2 Inference with a Uniform prior reduces to likelihood maximization 249
 - 7.2.3 Inferring the center of a distribution 249
 - 7.2.4 Parameter estimation and credible intervals 250
 - 7.2.5 Binning data reduces its information content 250
- 7.3 Localization of a Single Fluorophore 251
 - 7.3.1 Localization is an inference problem 251

7.3.2	Formulation of a probabilistic model	252
7.3.3	Maximum-likelihood analysis of image data	253
7.3.4	Results for molecular motor stepping	255
7.4	Localization Microscopy	256
7.5	Defocused Orientation Imaging	258
	Big Picture	260
	Key Formulas	261
	Track 2	262
7.3.2'a	Airy point spread function	262
7.3.2'b	Anisotropic point spread function	262
7.3.2'c	Other tacit assumptions	262
7.3.3'	Advantages of the maximum likelihood method	262
7.3.4'	Background estimation	263
7.4'	Interferometric PALM imaging	263
7.5'	More about anisotropy	266

Problems 267

Chapter 8 | Imaging by X-Ray Diffraction 272

8.1	Signpost: <i>Inversion</i>	272
8.2	It's Hard to See Atoms	273
8.3	Diffraction Patterns	274
8.3.1	A periodic array of narrow slits creates a diffraction pattern of sharp lines	274
8.3.2	Generalizations to the setup needed to handle x-ray crystallography	276
8.3.3	An array of slits with substructure gives a diffraction pattern modulated by a form factor	277
8.3.4	A 2D "crystal" yields a 2D diffraction pattern	278
8.3.5	3D crystals can be analyzed by similar methods	278
8.4	The Diffraction Pattern of DNA Encodes Its Double-Helical Character	279
8.4.1	The helical pitch, base pair rise, helix offset, and diameter of DNA can be obtained from its diffraction pattern	280
8.4.2	Accurate determination of size parameters led to a breakthrough on the puzzle of DNA structure and function	282

Big Picture 283

Key Formulas 283

Track 2 285

8.3.3'	Factorization of amplitudes	285
8.4.1'a	How to treat fiber samples of DNA	285
8.4.1'b	The phase problem	286

Problems 287

Chapter 9 | Vision in Dim Light 290

9.1	Signpost: <i>Construction</i>	290
9.2	The Edge of Vision	290
9.2.1	Many ecological niches are dimly lit	290
9.2.2	The single-photon challenge	291
9.2.3	Measures of detector performance	292
9.3	Psychophysical Measurements of Human Vision	293
9.3.1	The probabilistic character of vision is most evident under dim-light conditions	293
9.3.2	Rod cells must be able to respond to individual photon absorptions	295

9.3.3	The eigengrau hypothesis states that true photon signals are merged with a background of spontaneous events	296
9.3.4	Forced-choice experiments characterize the dim-light response	298
9.3.5	Questions raised by psychophysical experiments	300
9.4	Single-Cell Measurements	300
9.4.1	Vertebrate photoreceptors can be monitored via the suction pipette method	300
9.4.2	Determination of threshold, quantum catch, and spontaneous signaling rate	302
9.4.3	Direct confirmation that the rod cell imposes no threshold	305
9.4.4	Additional single-cell results	305
9.4.5	Questions raised by the single-cell measurements	308
	Big Picture	308
	Key Formulas	309
	Track 2	311
9.4.2'a	The fraction of light absorbed by a sample depends exponentially on thickness	311
9.4.2'b	The quantum yield for rod signaling	312
9.4.2'c	Quantum catch for a single human rod cell under axial illumination	313
9.4.2'd	The whole-retina quantum catch is the product of several factors	313
	Problems	315

Chapter 10 | The Mechanism of Visual Transduction 318

10.1	Signpost: <i>Dynamic Range</i>	318
10.2	Photoreceptors	318
10.2.1	Photoreceptors are a specialized class of neurons	318
10.2.2	Each rod cell simultaneously monitors one hundred million rhodopsin molecules	320
10.3	Background: Cellular Control and Transduction Networks	321
10.3.1	Cells can control enzyme activities via allosteric modulation	321
10.3.2	Single-cell organisms can alter their behavior in response to environmental cues, including light	322
10.3.3	The two-component signaling pathway motif	323
10.3.4	Network diagrams summarize complex reaction networks	324
10.3.5	Cooperativity can increase the sensitivity of a network element	325
10.4	Photon Response Events Localized to One Disk	327
10.4.1	Step 1: photoisomerization of rhodopsin in the disk membrane	328
10.4.2	Step 2: activation of transducin in the disk membrane	329
10.4.3	Steps 3–4: activation of phosphodiesterase in the disk membrane, and hydrolysis of cyclic GMP in the cytosol	329
10.5	Events Elsewhere in the Rod Outer Segment	331
10.5.1	Ion pumps in the rod cell plasma membrane maintain nonequilibrium ion concentrations	331
10.5.2	Step 5: ion channel closing in the plasma membrane	332
10.6	Events at the Synaptic Terminal	334
10.6.1	Step 6: hyperpolarization of the plasma membrane	334
10.6.2	Step 7: modulation of neurotransmitter release into the synaptic cleft	335
10.7	Summary of the Visual Cascade	337
	Big Picture	338
	Key Formulas	340
	Track 2	341
10.2.2'	Higher light intensities	341
10.3.3'a	More about two-component signaling pathways	341
10.3.3'b	Phototaxis	341

- 10.3.4' More about adaptation in chemotaxis 341
- 10.4.1' Cone and cone bipolar cells 344
- 10.4.3' Recently discovered vertebrate photoreceptors 345
- 10.6' Glutamate removal 345
- 10.7'a Termination of the photoreceptor response 346
- 10.7'b Negative feedback implements adaptation and standardizes signals from rod cells 346
- 10.7'c Recycling of retinal 348

Problems 350

Chapter 11 | The First Synapse and Beyond 352

- 11.1 Signpost: *False Positives* 352
- 11.2 Transmission at the First Synapse 352
 - 11.2.1 The synapse from rod to rod bipolar cells inverts its signal via another G protein cascade 352
 - 11.2.2 The first synapse also rejects rod signals below a transmission breakpoint 353
- 11.3 Synthesis of Psychophysics and Single-Cell Physiology 355
 - 11.3.1 Why does vision require about ten captured photons? 356
 - 11.3.2 Review of the eigengrau hypothesis 356
 - 11.3.3 Single-rod measurements constrain the fit parameters in the eigengrau model 358
 - 11.3.4 Processing beyond the first synapse is highly efficient 358
- 11.4 A Multistep Relay Sends Signals on to the Brain 360
 - 11.4.1 The classical rod pathway implements the single-photon response 360
 - 11.4.2 Other signaling pathways 361
 - 11.4.3 Optogenetic retinal prostheses 361
- 11.5 Evolution and Vision 362
 - 11.5.1 Darwin's difficulty, revisited 362
 - 11.5.2 Parallels between vision, olfaction, and hormone reception 364

Big Picture 366

Key Formulas 367

Track 2 368

- 11.2.2'a Instrumental noise 368
- 11.2.2'b Quantal release noise 368
- 11.2.2'c Mechanism of discrimination at the first synapse 368
- 11.2.2'd Why discrimination at the first synapse is advantageous 368
- 11.2.2'e Thresholding at later stages of processing 369
- 11.3.4' Psychophysics with single photon stimuli 369
- 11.4.1'a ON and OFF pathways 369
- 11.4.1'b Image processing in the retina 370
- 11.5.1' Rhabdomeric photoreceptors 373

Problems 375

PART III Advanced Topics

Chapter 12 | Electrons, Photons, and the Feynman Principle 381

- 12.1 Signpost: *Universality* 381
- 12.2 Electrons 382
 - 12.2.1 From paths to trajectories 382
 - 12.2.2 The action functional singles out classical trajectories as its stationary points 382

12.2.3	The Feynman principle expresses probability amplitudes as sums over trajectories	384
12.2.4	States and operators arise from partial summation over trajectories	384
12.2.5	Stationary states are invariant under time evolution	385
12.2.6	A confined-electron problem	385
12.2.7	Light absorption by ring-shaped molecules	387
12.2.8	The Schrödinger equation emerges in the limit of an infinitesimal time step	389
12.3	Photons	391
12.3.1	The action functional for photon trajectories	392
12.3.2	The special case of a monochromatic light source reduces to our earlier formulation	394
12.3.3	Vista: reflection, transmission, and the index of refraction	394
	Big Picture	397
Chapter 13 Field Quantization, Polarization, and the Orientation of a Single Molecule 398		
13.1	Signpost: <i>Fields</i>	398
13.2	A Single Molecule Emits Photons in a Dipole Distribution	399
13.3	Classical Field Theory of Light	399
13.4	Quantization Replaces Field Variables by Operators	401
13.5	Photon States	403
13.5.1	Basis states can be formed by applying creation operators to the vacuum state	403
13.5.2	Coherent states mimic classical states in the limit of large occupation numbers	405
13.6	Interaction with Electrons	406
13.6.1	Classical interactions involve adding source terms to the field equations	406
13.6.2	Electromagnetic interactions can be treated perturbatively	407
13.6.3	The dipole emission pattern	408
13.6.4	Electrons and positrons can also be created and destroyed	409
13.7	Vistas	409
13.7.1	Connection to the approach used in earlier chapters	409
13.7.2	Some invertebrates can detect the polarization of light	410
13.7.3	Invertebrate photoreceptors have a different morphology from vertebrates'	410
13.7.4	Polarized light must be used for single photoreceptor measurements	412
13.7.5	Some transitions are far more probable than others	412
13.7.6	Lasers exploit a preference for emission into an already occupied state	413
13.7.7	Fluorescence polarization anisotropy	413
	Big Picture	414
Chapter 14 Quantum-Mechanical Theory of FRET 415		
14.1	Signpost: <i>Decoherence</i>	415
14.2	Two-state Systems	415
14.2.1	FRET displays both classical and quantum aspects	415
14.2.2	An isolated two-state system oscillates in time	416
14.2.3	Environmental effects modify the behavior of a two-state system in solution	417
14.2.4	The density operator summarizes the effect of the environment	417
14.2.5	Time development of the density operator	418
14.3	FRET	419
14.3.1	The weakly coupled, strongly incoherent limit displays first-order kinetics	419
14.3.2	Förster's formula arises in the electric dipole approximation	420
14.3.3	More realistic treatment of the role of FRET in photosynthesis	421
	Big Picture	422

Epilogue 423

Acknowledgments 427

Appendix A | Global List of Symbols 431

A.1 Mathematical Notation 431

A.2 Network Diagrams 433

A.3 Named Quantities 433

Appendix B | Units and Dimensional Analysis 439

B.1 Base Units 439

B.2 Dimensions Versus Units 440

B.3 About Graphs 441

B.3.1 Arbitrary units 442

B.3.2 Angles 442

B.4 Payoff 442

Appendix C | Numerical Values 446

C.1 Fundamental Constants 446

C.2 Optics 446

C.2.1 Index of refraction for visible light 446

C.2.2 Miscellaneous 447

C.3 Eyes 447

C.3.1 Geometric 447

C.3.2 Rod cells 447

C.3.3 Cone cells 448

C.3.4 Beyond photoreceptors 448

C.4 B-Form DNA 448

Appendix D | Complex Numbers 449
